Contents

- **Cheng I. and Zhang L., 2016. Long-term air concentrations, wet deposition, and scavenging ratios of inorganic ions, HNO₃ and SO₂ and assessment of aerosol and precipitation acidity at Canadian rural locations. *Atmos. Chem. Phys. Discuss.*, doi:10.5194/acp-2016-918.**
- **Yao X. and Zhang L., 2016. Trends in atmospheric ammonia at urban, rural and remote sites across North America. *Atmos. Chem. Phys.*, 16, 11465-11475.**

Goals

First study:

- Analyze long-term geographical and temporal trends of NO_3^- and NH_4^+ in atmosphere and wet deposition in Canada
- Determine scavenging ratios of NO_3^- and HNO_3
- Estimate the relative contributions of particulate and gaseous nitrogen species to total nitrate and ammonium wet deposition.

Second Study

- Explore long-term trends of NH_3 and related causes at monitoring sites in Canada and U.S.
- Assess the uncertainties between different trend analysis tools

Methodology

First study:

- Daily air and wet deposition samples for major inorganic ions and trace gases. Valid air concentrations from 1983-2010 at 16 sites and precipitation measurements from 1984-2011 at 30 sites
- Temporal trends analysis using regression and the Mann-Kendall analysis (Gilbert, 1987)
- Monthly scavenging ratios - a pollutant's concentration in precipitation to that in air
- Relative contributions of gaseous and particulate species to nitrate and ammonium wet deposition using the scavenging ratio approach:

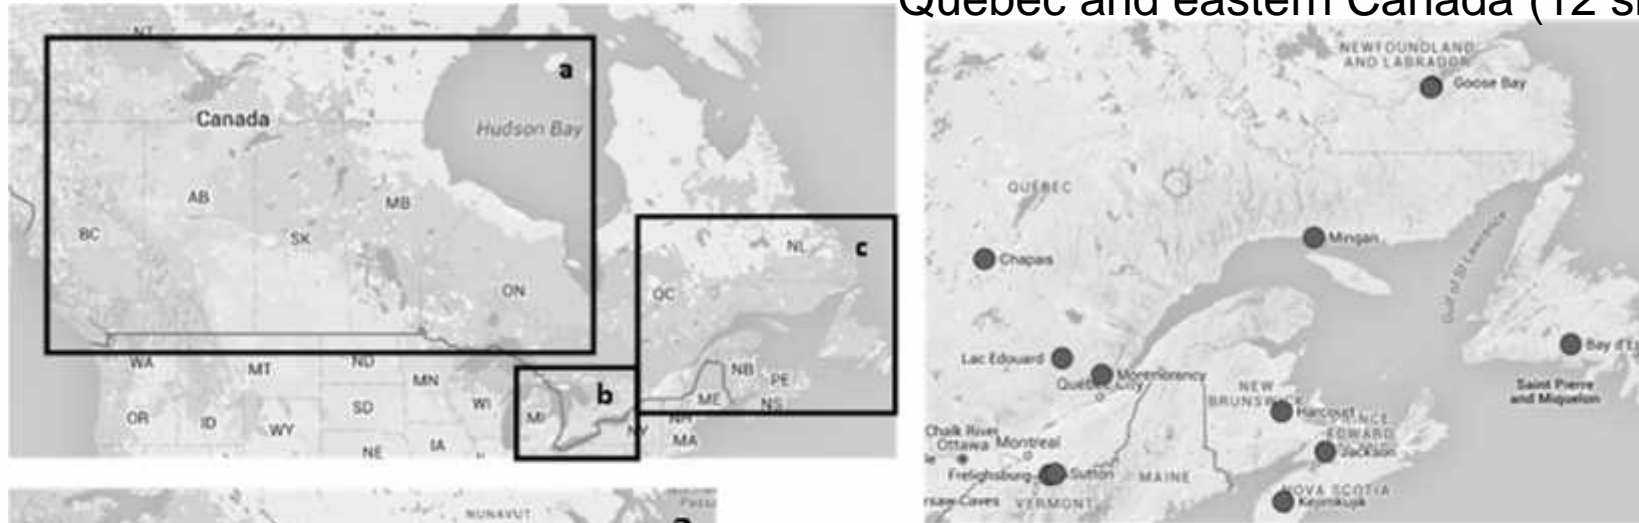

$$[\text{pNO}_3^-]_{\text{prec}} = W_{\text{fPM}} [\text{pNO}_3^-]_{\text{air}} P_f + W_{\text{cPM}} [\text{pNO}_3^-]_{\text{air}} (1-P_f),$$
$$[\text{HNO}_3]_{\text{prec}} = [\text{total NO}_3^-]_{\text{prec}} - [\text{pNO}_3^-]_{\text{prec}}$$

Second study:

- Ammonia trend analysis using two trend analysis tools: Mann-Kendall analysis (Gilbert, 1987) and the Ensemble Empirical Mode Decomposition (Wu et al., 2009)

Map of 30 CAPMoN sites

Quebec and eastern Canada (12 sites)

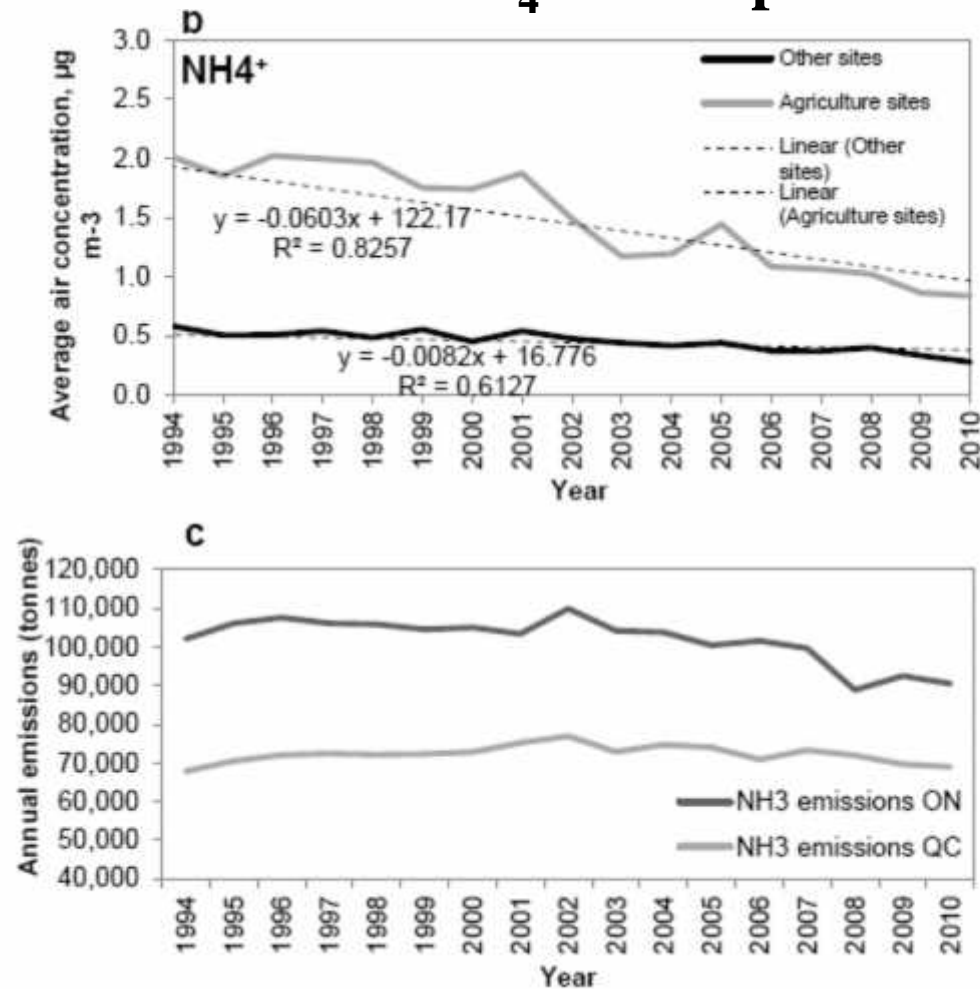

western/central Canada (10 sites)

southern Ontario (8 sites)

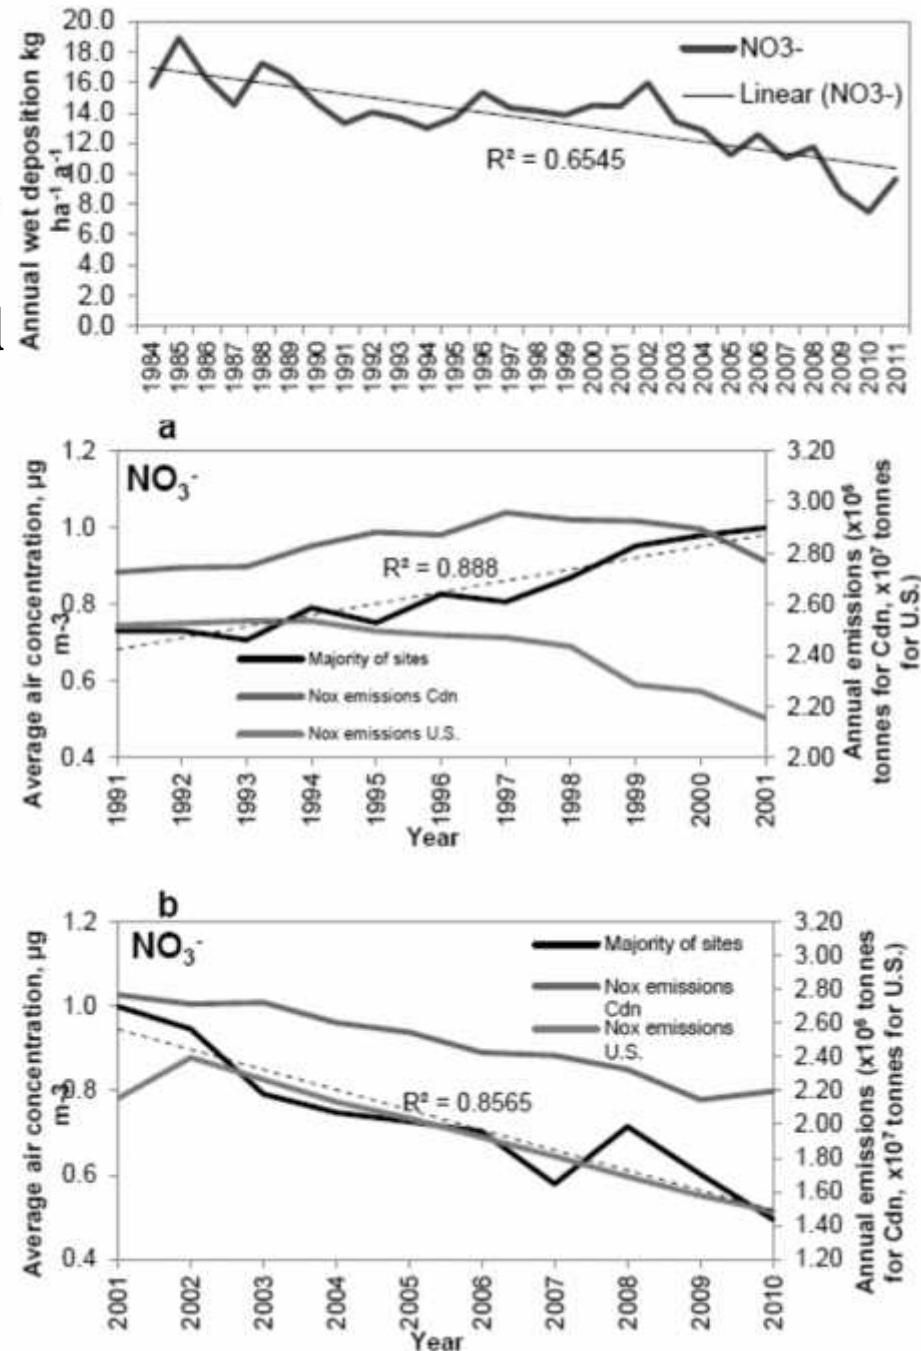

Results

Widespread decline in atmospheric NH_4^+ in Canada, no significant trend in NH_4^+ wet deposition

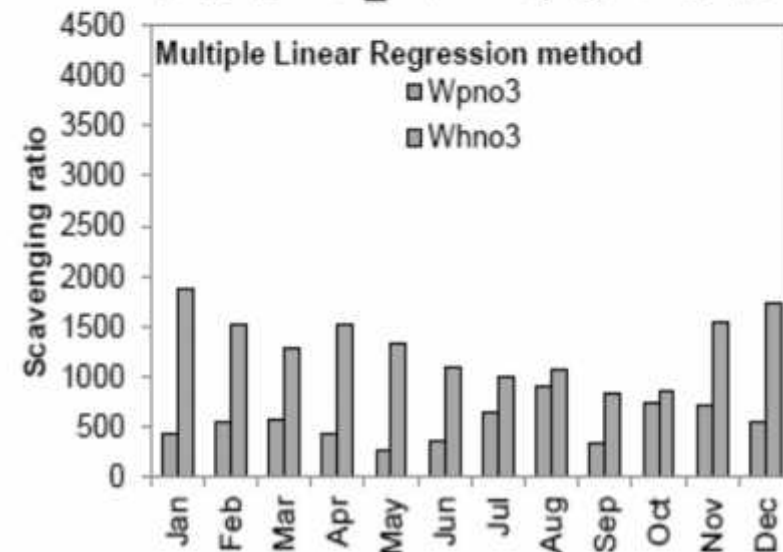

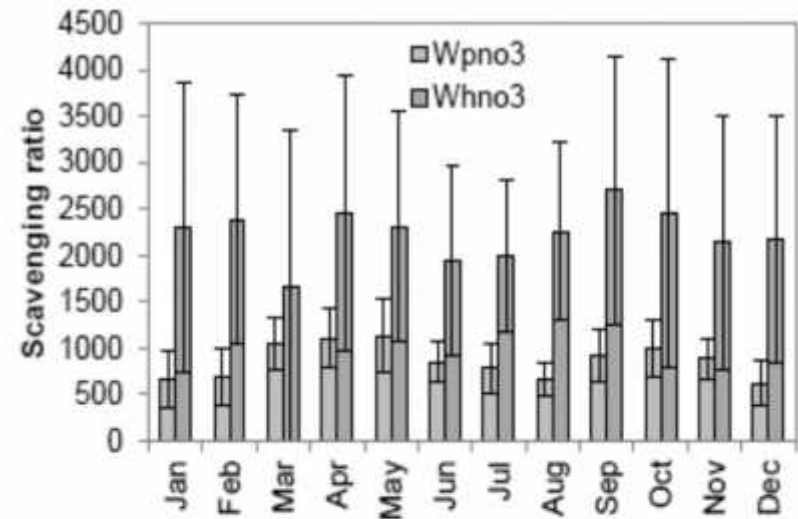

Results

- Widespread decline in annual NO_3^- wet deposition, but different trends in air concentration before and after 2001
- The highest annual wet deposition rates for NH_4^+ and NO_3^- were found in southeastern Canada closest to industrial and urban areas

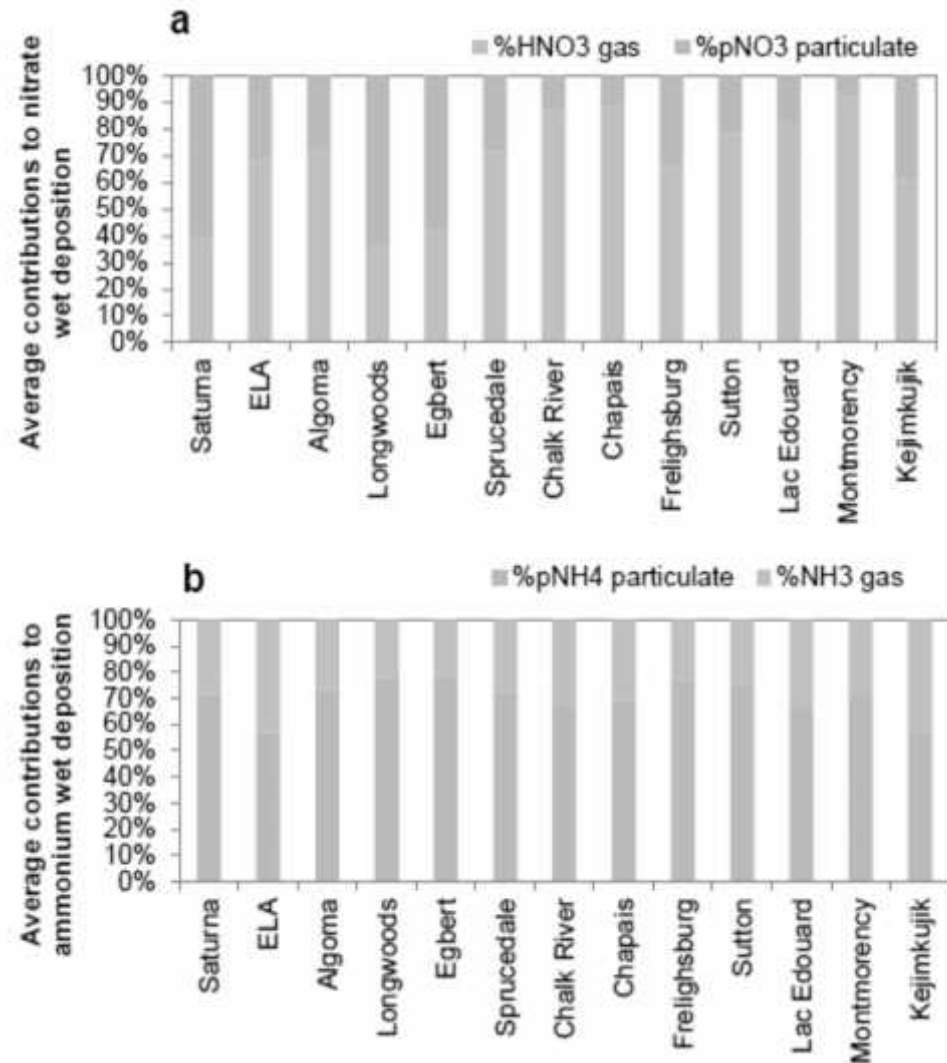

Results

- Average scavenging ratio of HNO_3 was greater than pNO_3^-
- Most W_{pNO_3} in literature are determined from total nitrate in precipitation and pNO_3^- in air, which overestimates W_{pNO_3} (by a factor of 6 on average)
- When wet NH_3 scavenging is excluded, scavenging ratios of NH_4^+ can be overestimated by 4-48% (average: 22%).

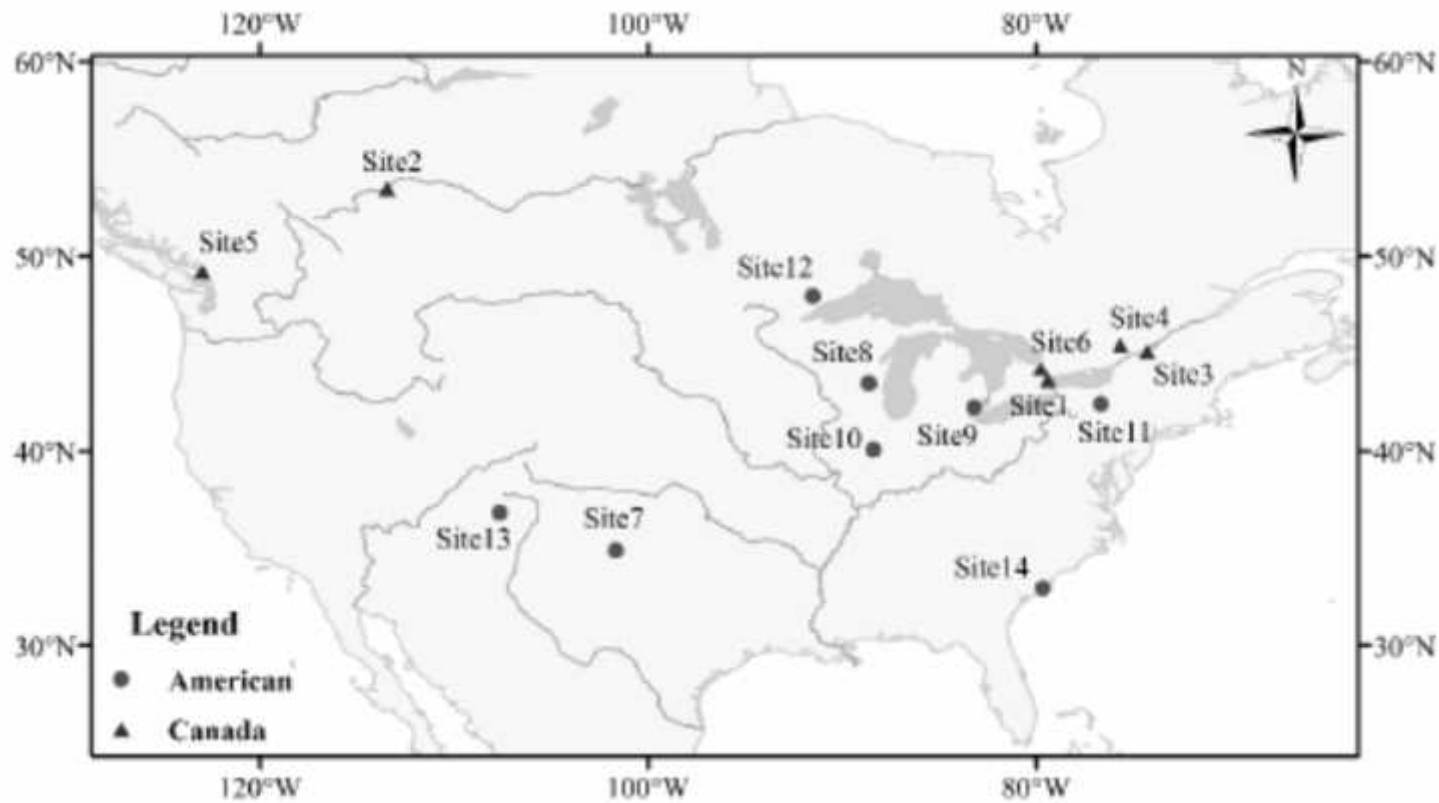

Results

- Average contribution to nitrate wet deposition: $28 \pm 23\%$ from pNO_3^- and $72 \pm 23\%$ from HNO_3
- Wet scavenging of pNO_3^- was higher at the sites closest to industrial and urban areas and at coastal sites
- Average contribution to ammonium wet deposition: $70 \pm 19\%$ from pNH_4^+ and $30 \pm 19\%$ from NH_3
- Particulate contributions were greater during cold months and lower during summer.

Map of sites with NH₃ data

Six Canadian sites and eight U.S. sites (> 7-year data)

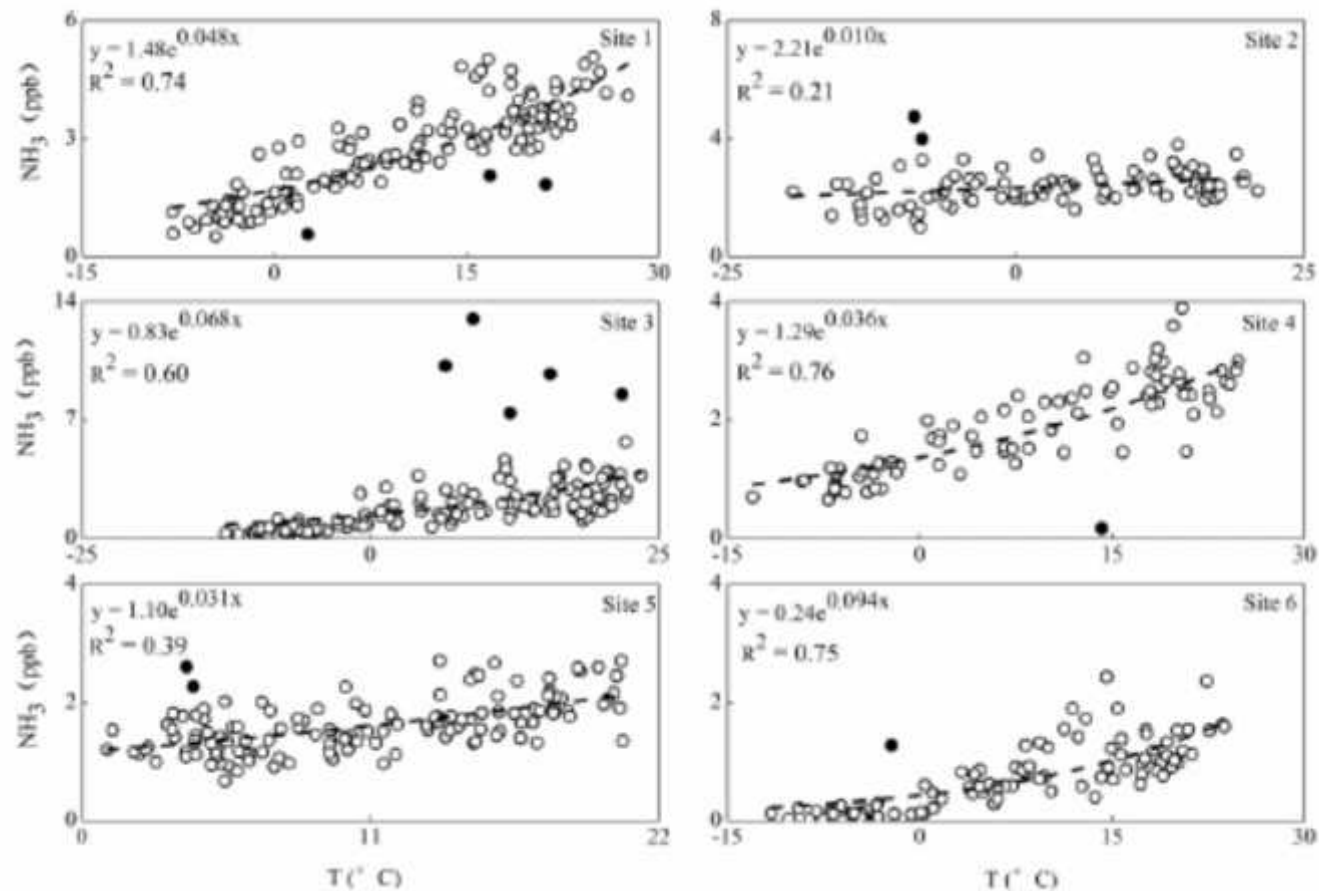

Results

Monthly average NH_3 and long-term trend extracted using Ensemble Empirical Mode Decomposition at the eight U.S. sites.

Results

Exponential correlations between atmospheric NH_3 and T at six Canadian sites

Results (second study)

- Moderate exponential correlations between atmospheric NH_3 and ambient T were found at nine sites - local biogenic emissions and/or $\text{NH}_3/\text{NH}_4^+$ partitioning were likely dominant factors at these sites.
- At the four Canadian sites, no decreasing trends in atmospheric NH_3 were found despite significant decreases in anthropogenic NH_3 emissions from main sectors in the last decade. The decreased NH_3 anthropogenic emission was compensated or overwhelmed by the increased biogenic emission and/or changes in $\text{NH}_3/\text{NH}_4^+$ partitioning. This was supported by pNH_4^+ data which exhibited a decreasing trend, likely caused by a combination of reduced SO_2 and NO_x emission and increased temperature.
- The M-K analysis showed an increasing trend in atmospheric NH_3 at seven out of the eight U.S. sites, which was also supported by the EEMD-extracted results.
- NH_3 increased by 20-50% from 2008 to 2015 at the three rural/agriculture sites and by 100%-200% at the four remote sites.
